## *Log-Probability of the data given the model (marginal likelihood)*

Use this value for Bayes factor calculations:

$BF = \text{Exp}[\ln(\text{Prob}(D | \text{thisModel}) - \ln(\text{Prob}(D | \text{otherModel}))$

or as  $LBF = 2(\ln(\text{Prob}(D | \text{thisModel}) - \ln(\text{Prob}(D | \text{otherModel}))$

shows the support for thisModel]

(1a, 1b and 2) is an approximation to the marginal likelihood, make sure the program run long enough!

(1a, 1b) and (2) should give a similar result, (2) is considered more

crude than (1), but (1) needs heating with several well-spaced chains,

(1b) is using a Bezier-curve to get better approximations for runs with low number  
of heated chains

You should most likely rerun your analysis after improving run parameters.
